# Patagonia parrots density analysis

Francisco Dénes and Peter Sólymos

June 8, 2018

# Motivation

We want to model the density of the austral parakeet *Enicognathus ferrugineus* and the slender-billed parakeet *Enicognathus leptorhynchus* from count data obtained with road transect surveys in Patagonia. Because these parrots are gregarious, we want to assess whether group size and size of groups vary across habitats (classified as 'urban', 'agropastoral' and 'other' (i.e. various natural forest formations), and between breeding (Nov-Dec) and non-breeding seasons (Jan-Oct).

We use distance sampling methods to account for detectability of parrots.

These animals tend to form smaller or larger groups, but groups of size 2 are also often observed as a result of mating pairs, as shown in Figure 1.

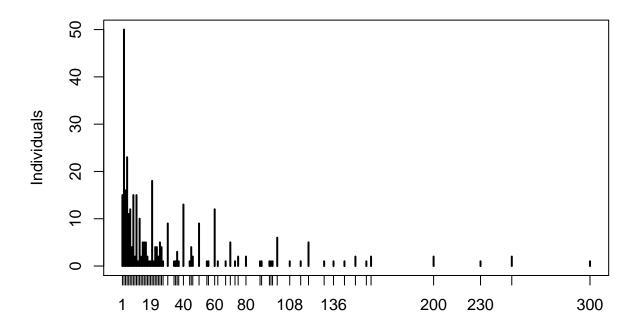

Figure 1: Enicognathus ferrugineus count frequencies

# Austral parakeet Enicognathus ferrugineus

## Estimating effective detection radius (EDR)

We fit distance sampling models with detection predictor variables, including the average group size, the number of groups that were observed (to account for the possibility that grouping behaviour influences detectability), and also habitat type. We used forward-stepwise model selection, starting with single covariate models and eliminating covariates that do not improve model parsimony (i.e. result in dAIC < 2) in relation to the null model.

Table 1: E. ferrugineous EDR models AIC

	$\mathrm{d}\mathrm{f}$	AIC	dAIC
EDR.habitatype	3	1434.532	0.00
EDR.null	1	1438.166	3.63
EDR.avggroupsize	2	1439.144	4.61
EDR.numbergroups	2	1440.166	5.63

The model (EDR.habitatype) has the lowest AIC (Table 1), indicating that habitat type affects the effective detection radius (EDR) of *Enicognathus ferrugineus*. Specifically, detection radius is higher in agropastoral than urban and other habitats (Table 2). This means that detectability is higher in agropastoral habitats, and also that the area surveyed in a given sample unit is larger if the habitat therein is agropastoral vs. urban or other, presubably because it is possible to see further in pastures and planted fields than in forest or urban environments.

Table 2: E. ferrugineous top-ranked EDR model estimates

	Estimate	Std. Error	z value	Pr(> z )
log.tau_(Intercept)	4.589	0.038	119.365	0.000
log.tau_Urban	0.057	0.058	0.988	0.323
$log.tau\_Agropastoral$	0.263	0.103	2.556	0.011

Table 3: E. ferrugineous habitat-specific EDR (m)

Habitat	EDR
Other	98.36847
Urban	104.18432
Agropastoral	127.92056

## Models for number of groups

We then model the number of groups as a function of covariates. The model for number of groups is  $G_i \sim \operatorname{Poisson}(D_i A_i)$ , where  $D_i = \operatorname{covariates}$  and  $A_i = \operatorname{area}$  sampled in site *i*.  $A_i$  is calculated using the habitat-specific estimated EDR, and is added to the model as an offset.

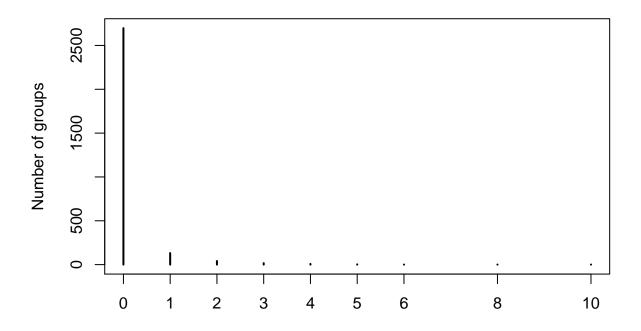

Figure 2: Enicognathus ferrugineus group numbers

#### Model selection

For number of groups, we use a stage-wise selection procedure. First, we build a first set of models to evaluate the effect of covariates related to habitat (habitat type and elevation).

Table 4: E. ferrugineous number of group models

	df	AIC	dAIC
ngroup.hab.ele2	5	2082.963	0.00
ngroup.hab.ele	4	2114.437	31.47
ngroup.hab	3	2133.717	50.75
ngroup.ele2	3	2275.565	192.60
ngroup.ele	2	2323.806	240.84

The model with both habitat type and elevation (quadratic effect) has the lowest AIC (Table 4), indicating that both covariates affect the number of groups:

Table 5: E. ferrugineous 'ngroup.hab.ele2' model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	-3.108	0.233	-13.356	0

	Estimate	Std. Error	z value	Pr(> z )
habitatOther	1.507	0.202	7.455	0
habitatUrban	2.390	0.202	11.823	0
elevation	-0.004	0.001	-7.032	0
I(elevation^2)	0.000	0.000	5.947	0

Table 6: Deviance partitioning of 'ngroup.hab.ele2' model for  $\it E. ferrugineous$ 

	Df	Deviance	Resid. Df	Resid. Dev
NULL	NA	NA	2900	1865.338
habitat	$^2$	207.965	2898	1657.373
elevation	1	21.279	2897	1636.094
I(elevation^2)	1	33.475	2896	1602.619

We then proceed by adding within-year temporal covariates (breeding/non-breeding season and julian date) and their interactions with habitat.

Table 7:  $E.\ ferrugineous$  number of group models (within-year temporal predictors) AIC

	df	AIC	dAIC
ngroup.habXseason.ele2	8	2065.594	0.00
ngroup.hab.season.ele2	6	2067.555	1.96
ngroup.habXjdate.ele2	8	2081.546	15.95
ngroup.hab.ele2	5	2082.963	17.37
ngroup.hab.jdate.ele2	6	2084.491	18.90

The model with the season\*habitat interaction (Table 8) is equally parcimonious with the model with only the additive effects (Table 9). Given these are nested models, this indicates the interaction only marginally improves the model fit, so will continue with model with season and no interaction:

Table 8:  $E.\ ferrugineous$  'ngroup.hab Xseason.ele2' interaction model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	-18.187	558.012	-0.033	0.974
elevation	-0.004	0.001	-6.547	0.000
I(elevation <sup>2</sup> )	0.000	0.000	5.500	0.000
habitatOther	15.797	558.012	0.028	0.977
habitatUrban	2.008	908.375	0.002	0.998
seasonnon-breeding	15.186	558.012	0.027	0.978
habitatOther:seasonnon-breeding	-14.357	558.012	-0.026	0.979
habitatUrban:seasonnon-breeding	0.266	908.375	0.000	1.000

Table 9:  $E.\ ferrugineous$  'ngroup.hab.season.ele2' additive model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	-4.250	0.412	-10.318	0.000
habitatOther	1.510	0.204	7.411	0.000
habitatUrban	2.314	0.203	11.424	0.000
elevation	-0.004	0.001	-6.408	0.000
I(elevation^2)	0.000	0.000	5.365	0.000
seasonnon-breeding	1.175	0.340	3.451	0.001

Finally, we assess year effects by adding a year covariate (2013-2016).

Table 10:  $E.\ ferrugineous$  number of group models (year predictor) AIC table

	df	AIC	dAIC
ngroup.hab.season.ele2.year	9	2022.265	0.00
ngroup.hab.season.ele2	6	2067.555	45.29

The model with lowest AIC indicates that the number of groups is affected by habitat ype, elevation, season (breeding/non breeding) and year.

Table 11:  $E.\ ferrugineous$  top-ranked (ngroup.hab.season.ele2.year) model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$

## Models for group size

The count distribution is characterized with a spike at 2 (Figure 1), and by the absence of 0s due to group size being conditional on having >0 birds to consider it a group.

We start developing a general V-Inflated Poisson (VIP) model ("V" stands for "variable"", in referce to the "Z" representing 0 in a zero-inflated Poisson model, or ZIP), then we add the >0 condition.

R functions for the VIP model are presented at the end of this document, including simulations to check the estimating procedure.

#### Maximum likelihood

Let Y be a random variable, and y are observations, V is the count value that has some extra probability mass  $(V=0 \text{ is the ZIP model}), f(y;\lambda)$  is the Poisson density  $(f(y;\lambda)=e^{-\lambda}\frac{\lambda^y}{y!}).$ 

The V-Inflated density can be written as  $P(Y = y) = \phi I(Y = V) + (1 - \phi)f(y; \lambda)$  which is  $\phi + (1 - \phi)f(V; \lambda)$ when Y = V and  $(1 - \phi) f(y; \lambda)$  otherwise.

We define the extra probability mass at V=2 to account for the group size peak in pairs. The model is also truncated at 0, because there are no groups with 0 individuals. We include habitat type as a covariate for the count (Poisson) component, and compare models with and without season (breeding/non-breeding) as a covariate for the V-inflation probability.

Estimate Std. Error z value  $\Pr(>|z|)$ P (Intercept) 1.000 0.019 52.686 0.000P Urban 1.754 0.02376.4830.000P Agropastoral 16.744 0.000 0.6120.037V\_(Intercept) 1.612 0.107

0.000

1.316

-3.474

Table 13: E. ferrugineous group size model estimates

Estimated model coefficients (Table 13) indicate that group sizes are larger in urban ( $\beta = 1.754$ ) and agropastoral ( $\beta = 1.754$ ) habitats when compared to other natural habitats. Moreover, the probability of there being extra pairs (i.e. the V-inflation probability,  $\phi$ ) is smaller in the non-breeding season ( $\beta = 1.754$ ).

Considence intervals (CI) based on estimated standard errors can be obtained (Table 14):

V seasonnon-breeding

Table 14: E. ferrugineous group size model CI

	2.5%	97.5%
P_(Intercept)	0.963	1.037
P_Urban	1.709	1.799
P_Agropastoral	0.540	0.683
$V_{\underline{\hspace{0.5cm}}}(Intercept)$	-0.284	2.915
V_seasonnon-breeding	-5.118	-1.830

Alternatively, we can estimate confidence intervals based on quantiles using bootstrap samples (with n=250) for the estimated coefficients (Table 15).

Table 15: Estimated coefficients and 95% CI based on bootstrap sample (n=250) quantiles for *E. ferrugineous* group size models

	Estimate	2.5%	97.5%
P_(Intercept)	1.000	-20.137	28.356

# Slender-billed parakeet Enicognathus leptorhynchus

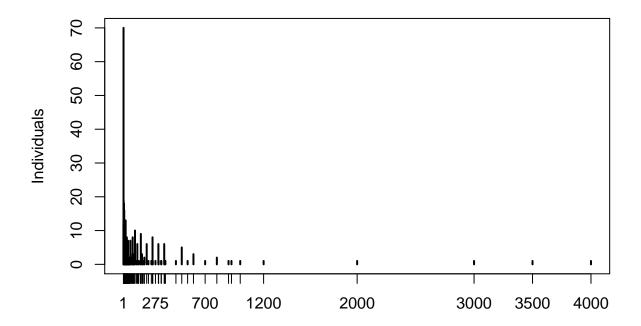

Figure 3: Enicognathus leptorhynchus count frequencies

# Estimating effective detection radius (EDR)

We follow the same procedure used for the austral parakeet above.

Table 16: E. leptorhynchus EDR models AIC

	df	AIC	dAIC
EDR.avggroupsize.habitat	4	1054.464	0.00
EDR.habitat.avggroupsize.numbergroups	5	1059.062	4.60
EDR.avggroupsize	2	1063.875	9.41
EDR.avggroupsize.numbergroups	3	1064.553	10.09
EDR.habitat.numbergroups	4	1069.376	14.91
EDR.habitatype	3	1070.755	16.29
EDR.null	1	1086.330	31.87
EDR.numbergroups	2	1087.172	32.71

The model (EDR.avggroupsize.habitat) has the lowest AIC (Table 16), indicating that habitat type and average group size affect the effective detection radius (EDR) of *Enicognathus leptorhynchus*. The mean EDR for each habitat, predicted using model coefficients and the habitat-specific means of average group size, is shown in Table 17.

Table 17: E. leptorhynchus top-ranked EDR model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
log.tau_(Intercept)	5.361	0	1.273654e + 51	0
log.tau_gavg	0.001	0	9.610881e + 50	0
log.tau_Urban	-0.266	0	-6.308165e+49	0

Table 18: E. leptorhynchus habitat-specific mean EDR (m)

EDR
235.4183
224.2124
180.7002

# Models for number of groups

As for the austral parakeet, the model for number of groups is  $G_i \sim Poisson(D_iA_i)$ , where  $D_i = covariates$  and  $A_i = area$  sampled in site i.  $A_i$  is calculated using the habitat-specific estimated EDR, and is added to the model as an offset.

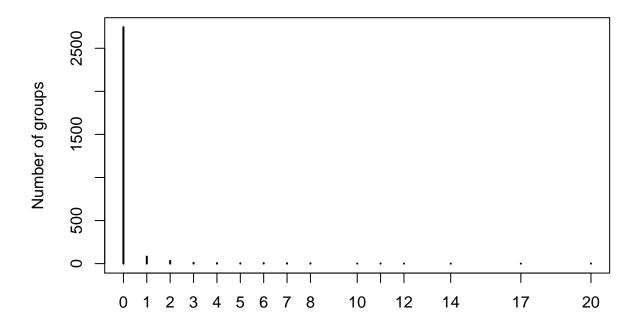

Figure 4: Enicognathus leptorhynchus group numbers

#### Model selection

First set of models to evaluate the effect of habitat type and elevation covariates (Table 18):

Table 19: E. leptorhynchus number of group models

	df	AIC	dAIC
ngroup.hab.ele2	5	2486.990	0.00
ngroup.hab.ele	4	2487.834	0.84
ngroup.hab	3	2493.346	6.36
ngroup.ele2	3	2746.031	259.04
ngroup.ele	2	2761.122	274.13

The models 'ngroup.hab.ele' (with linear elevation effect) and 'ngroup.hab.ele2' (with quadratic effect) are equally parsimonious (Table 18), but the quadratic term in the latter is mostly uniformative (Tables 19-20). Given these are nested models, we drop the quadratic term and continue with the model with habitat and linear elevation effects.

Table 20: E. leptorhynchus 'ngroup.hab.ele' model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	-2.781	0.123	-22.568	0.000
habitatOther	-2.035	0.147	-13.874	0.000
habitatUrban	-0.734	0.143	-5.116	0.000
elevation	0.000	0.000	2.736	0.006

Table 21: Deviance partitioning of 'ngroup.hab.ele' model for  $\it E.\ leptorhynchus$ 

	Df	Deviance	Resid. Df	Resid. Dev
NULL	NA	NA	2900	2358.856
habitat	2	270.326	2898	2088.530
elevation	1	7.512	2897	2081.018

Adding within-year temporal covariates (breeding/non-breeding season and julian date) and their interactions with habitat:

Table 22:  $E.\ leptorhynchus$  number of group models (within-year temporal predictors) AIC

	df	AIC	dAIC
ngroup.habXjdate.ele	7	2110.653	0.00
ngroup.hab.ele.jdate	5	2230.345	119.69
ngroup.habXseason.ele	7	2472.731	362.08
ngroup.hab.ele	4	2487.834	377.18
ngroup.hab.ele.season	5	2489.059	378.41

The model 'ngroup.habXjdate.ele' has the lowest AIC (Table 21).

Table 23: E. leptorhynchus 'ngroup.habXjdate.ele' model estimates

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	-1.463	0.167	-8.741	0.000
elevation	0.000	0.000	1.939	0.053
habitatOther	2.234	0.590	3.788	0.000
habitatUrban	0.412	0.310	1.329	0.184
jdate	-0.006	0.001	-10.029	0.000
habitatOther:jdate	-0.040	0.007	-5.589	0.000
habitatUrban:jdate	-0.009	0.002	-4.095	0.000

Finally, we assess year effects by adding a year covariate (2013-2016).

Table 24:  $E.\ leptorhynchus$  number of group models (year predictor) AIC table

	df	AIC	dAIC
ngroup.habXjdate.ele.year	8	1993.981	0.00
ngroup.hab X j date.ele	7	2110.653	116.67

The best-ranked model indicates that the number of groups is affected by habitat type, elevation, julian date and year (Tables 23-24).

Table 25: E. leptorhynchus 'ngroup.hab Xjdate.ele.year' model estimates

	Estimate	Std. Error	z value	Pr(> z )
(Intercept)	-3.952	0.264	-14.974	0.000
habitatOther	-1.629	0.150	-10.893	0.000
habitatUrban	-0.506	0.144	-3.507	0.000
elevation	0.000	0.000	2.851	0.004
seasonnon-breeding	-0.749	0.201	-3.723	0.000
as.factor(year)2014	0.669	0.276	2.422	0.015
as.factor(year)2015	1.763	0.237	7.452	0.000
as.factor(year) 2016	3.280	0.239	13.705	0.000

Table 26: Deviance partitioning of 'ngroup.habXjdate.ele.year' model for  $E.\ leptorhynchus$

#### Zero-truncated VIP

We can truncate counts to be larger than 0. We also need V > 0 (for V = 0 case, look into ZIP or conditional Poisson model). Conceptually, the V-Inflation follows the 0-truncation (because we cannot observe 0, real truncated distribution).

The 0-truncated PDF is  $P(Y=y\mid Y>0)=\frac{P(Y=y)}{1-P(Y=0)}$ . The 0-truncated V-Inflated density is  $P(Y=y\mid Y>0,V>0)=\phi I(Y=V)+(1-\phi)\frac{f(y;\lambda)}{1-f(0;\lambda)}$ . This can be achieved in the vip call by the argument truncate=TRUE.

Here we use covariates for both the V and non-V part.

```
set.seed(1)
